TITLE: Water Resources of the Ukrainian Poles'ye and their Utilization (Vodnyye resursy Ukrainskogo Poles'ya i ikh ispol'zovaniye)

PERIODICAL: In Sbornik: Narisi pro prirodu i sil's'ke gospodarstvo Ukr. Polissya. Kiyev, un-t, 1955, pp. 193-198 (Ukrainian text with Russian resumé)

ABSTRACT: The possibility of utilizing the water resources of the Ukrainian Poles'ye depends primarily on the proper drainage of swamps and boggy areas. The flatness of the country and the diversity of the soil covering creates problems in drainage engineering, which at the same time must be related to such agricultural problems as irrigation, river flow control, soil improvement measures, etc. A large part of the drainage system destroyed during the war has been restored and extensive new networks have been built. The flatness of the country makes it possible to utilize only 5-10% (in a few cases up to 25%).

TITLE: On the problem of continuous oxidization of cast iron elements by oxygen

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy. Chernaya metallurgiya, no. 12, 1960, 39 - 45

TEXT: Oxidation of iron by blowing oxygen in the spout of a blast furnace and cupola, in ladles and mixers had already been tried. The successful tests in steel production of blowing oxygen through barrel furnaces (Ref. 5: N. N. Lazarev, Stal', 1957, no. 5) has indicated practically possible ways of continuous steel production, but blowing in the barrel furnace is not possible with a strong blast because of metal and slag splashes, intense wear of lining and other reasons. In experiments described in this article oxygen was blown through the falling metal stream out of contact with the furnace walls (Fig. 1). The method is suggested for the treatment of iron before charging it into open-hearth furnaces, and it is expected that the productivity of an open-hearth furnace would be raised 25 - 40%.

Card 1/5

23618

S/148/60/000/012/004/020
A161/A133

On the problem of continuous oxidization of...

The shaft furnace illustrated may be considered the first stage in the continuous steel making process. The 1.23 m high test furnace was lined with fireclay brick, the well was lined with magnesite; had a water-cooled copper caisson (5 in Fig. 1) in the top containing a fireclay insert (6). Up to 100 kg iron was treated in each of the 16 test heats, using oxygen at 15 atm pressure. The first experiment series with bottom blowing gave results which were not completely satisfactory. In the second series combined bottom and top blowing proved better and the oxygen stream from the top had a better pulverizing effect on the metal, but it was not possible to use top blowing over 30% of the total because the metal splashed too strongly before the pouring spout. The temperature of the metal before entering the furnace was 1,200 - 1,300°C and increased by 200 - 300°C during blowing. In the third series it was attempted to determine the effect of the metal jet fall height at top blowing only. A uniform pouring rate was maintained by the use of an intermediate ladle (10, Fig. 1) and constant iron level in, but it was not possible to increase the furnace height further than up to 1.7 m, the difference not being noticeable. As the quantity of oxidized impurities was only half compared with the second series, it was obvious that the ef-

Card 2/5

S/148/60/000/012/004,020
A161/A133

On the problem of continuous oxidization of...

fect of bottom blowing had been underestimated. Fig. 3 shows the chosen furnace head design. The intake opening 30 mm in diameter and 65 mm in height was made in fireclay brick, and the brick was installed on the water-cooled caisson without the initial insert. The oxygen pressure in the reductor for bottom and top blowing was 14 - 15 atm. The variations of gas composition could not be determined because the process was too short. The high iron content in slag and brownish smoke indicated intense oxidization of iron in the process. The use of a container in the furnace shaft bottom seems advisable in which metal could react with ferrous slag. Conclusions: The oxidation of carbon in a falling iron stream is possible to 24 - 27%, of Si and Mn to 80%, and of P to 30 - 40%. Sulfur is eliminated to 30 - 40%. A higher degree of oxidization of elements is possible by the application of a space in the bottom furnace shaft portion, and of an additional pulverizing stage. The effect of the metal falling height must be studied on a larger scale than in these experiments. The burning of iron can be reduced by holding metal under slag in the additional space in the furnace shaft bottom. There are 3 figures, 4 tables and 5 references: 4 Soviet-bloc and 1 non-Soviet bloc.

TITLE: Scientific Explorations in Siberia (Nauchnye issledovaniya v Sibiri)

PERIODICAL: Priroda, 1958, Nr 7, pp 114-115 (USSR)

ABSTRACT: The XIIth Session of the Zapadno-Sibirskiy filial AN SSSR (West-Siberian Branch of the AS USSR) took place in Novosibirsk from 17 to 20 March 1958. Delegates from other important Soviet scientific centers attended the session. A total of 190 papers were delivered, of which over 50 served practical purposes. Professor T.F. Gorbachev, President of the Presidium of the West-Siberian Branch of the AS USSR and Vice-President of the Organization Committee of the Siberian Department of the AN USSR, evaluated the research results of the over 800 scientific workers of the institute, outlined the 1959 to 1965 plan assignments to the institute and commented on the establishment of the new large scientific center in the east of the country, the Sibirskoye otdeleniye AN SSSR (Siberian Department of the AS USSR). In the section for complex explorations of the water reservoir of the Novosibirskaya GES (Novosibirsk Hydroelectric Station), S.G. Beyrom and V.M. Samochkin spoke on the na-

TITLE: Catalysis of reactions in the solid state. Thermal decomposition of ammonium perchlorate in the presence of iron oxide

PERIODICAL: Kinetika i kataliz, v.4, no.1, 1963, 88-96

TEXT: The kinetics of the decomposition of pure NH_4ClO_4 were studied first. The decomposition between 215 and 234.5°C occurred to the extent of 31 to 34% with the activation energy ranging from 29.6 to 34.9 kcal/mole and induction periods from 61 to 218 min. Above 240°C the decomposition proceeded more rapidly, also to the extent of 31 to 33%, and with an activation energy of 31.6 kcal/mole. With the addition of Fe_2O_3 the decomposition below 240°C took place with shortened induction periods and slightly increased rates. For the mixtures containing 50% Fe_2O_3 the extent of the decomposition reached 40 to 45%. Between 240 and 300°C, 60 to 95% of NH_4ClO_4 was decomposed with short induction periods (9 to 23 minutes). The decomposition rate was doubled when the content of Fe_2O_3 increased from 2 to 20%.
Card 1/2

Catalysis of reactions ...

S/195/63/004/001/006/009
E075/E436

Mixtures containing 2, 5 and 12% Fe_2O_3 were also investigated between 300 and 380°C. At these temperatures the first stage of the reaction (approx. 30% decomposition) was completed in 2 to 3 min followed by a slow further decomposition. The activation energies were 40.9, 30.9, 25.7 and 22.0 kcal/mole for the mixtures containing 0, 2, 5 and 12.5% Fe_2O_3 . By comparing the activation energies for the decomposition of pure NH_4ClO_4 with those for the decomposition of its mixtures with Fe_2O_3 , it was concluded that the mechanism of decomposition of the mixtures is electronic by nature. Apparently Fe_2O_3 accelerates the transfer of electrons from anions to cations, i.e. it promotes the formation of NH_4 and ClO_4 radicals which decompose to gaseous products. There are 10 figures and 10 tables.

"Problems of the Indication of Surgery for hearing Correction."

Budapest, ORVOSGYOGS. Vol 14, No 4, Oct-Dec 62, pp 268-271.

Abstract: [Author's German summary] The fundamental problem of the indication of corrective surgery of the hearing organ arises from contradictions between older and modern views. Correction is to be carried out early, at a time when hearing is not yet impaired. Surgical treatment is indicated more and more in cases of mesotympanic processes which were treated exclusively conservatively in the past. Sufficient dosages of antibiotic medication should insure a safe operation. Finally, the social significance of the indication of operative correction is referred to. No references are given.

TITLE:

Thermal decomposition of ammonium perchlorate in the presence of zinc oxide

PERIODICAL: Magyar Kémiai Folyóirat, no. 10, 1961, 459 - 460

TEXT: The article deals with investigation of the decomposition process of ammonium perchlorate in the presence of zinc oxide. For their experiments, the authors used pure NH_4ClO_4 according to Merck standards, and samples in the form of pellets, containing pulverized ammonium perchlorate and zinc oxide in suitable proportion, produced at a pressure of 4 ton/cm². The 30% decomposition of pure ammonium perchlorate between 200 and 300°C increased to 85% between 200 and 240°C in the presence of zinc oxide. Experiments on the influence of the modified electric conductivity of zinc oxide on the decomposition of NH_4ClO_4 revealed that the rise in conductivity

Thermal decomposition of...

ity resulted in an increase of the reaction rate, the decrease of the conductivity in a decrease of the reaction rate and an increase in the induction period. On the other hand, the activation energy values remained practically unchanged as a result of the above variations. The explosion resulting from the mixture of NH_4ClO_4 and ZnO with a ratio between 300:1 and 10:1 was extremely violent and accompanied by flame. With a 50:50 ratio the decomposition of NH_4ClO_4 still resembled a mild explosion, while with a further increase of ZnO only a weak detonation took place. The experiments revealed furthermore, that the presence of only 0.2 % of zinc oxide set the explosion temperature of NH_4ClO_4 at about 240°C , which is 200°C less than quoted by A.K. Galwey and P. W. M. Jacobs (Ref. 5: J. Chem. Soc., 5031, 1960), who also stated that the proton transfer mechanism is the decisive factor in the explosion phenomena, whereas, in fact, the activation energy values

found by the authors are close to 32 kcal which corresponds to the electron transfer mechanism. Values of the activation energy of various samples are shown in Table 1 and 2. There are 2 tables, 2 figures and 5 references: 4 non-Soviet-bloc and 1 Soviet-bloc. Ther references to the English-language publications read as follows: L. L. Bircumshaw and B. H. Newman: Proc.
